Height
Seed mass
Leaf area, nitrogen

Project Overview

- **Problem Statement:** Create a process and model to predict 6 plant traits from plant images and associated ‘GeoData’.
 - Images from [iNaturalist](#), 512 x 512 RGB
 - GeoData based on image coordinates: Soil, Climate, Satellite, Radar measurements (*WORLDCLIM*, *SOIL*, *VOD*, *MODIS*)
 - Plant Traits targets: “chemical tissue properties loosely related to plant images” | [TRY database](#)
 - High accuracy not expected due to inherent heterogeneity of traits and plant images
- **Outcomes:**
 - Good start for outlier cleaning based on plant trait targets
 - Loosely optimized model architecture and multi-output regression strategy
 - Image+GeoData models performed better than GeoData only. Reasonable overall accuracy.

Data Wrangling, Preprocessing

- Images and GeoData provided by Kaggle competition organizers ([FGVC11](#) workshop at [CVPR 2024](#))
 - *Not saved in project repository*
- Outliers detected and removed based on plant trait targets. Distributions assessed alongside images for extreme values.
- GeoData grouped by measurement technique, normalized, then reduced via PCA
 - Seasonal features engineered for Satellite and Radar measurements

Example: Leaf Area Outliers

ID: 118451368 | 4.79e+05

ID: 192989017 | 4.79e+05

Area = 4.8e5 (cm²?)
Probably real value
Looks quite leafy

ID: 194099632 | 5.92e+05

ID: 192913870 | 5.92e+05

Increasing leaf area

ID: 194091952 | 6.85e+05

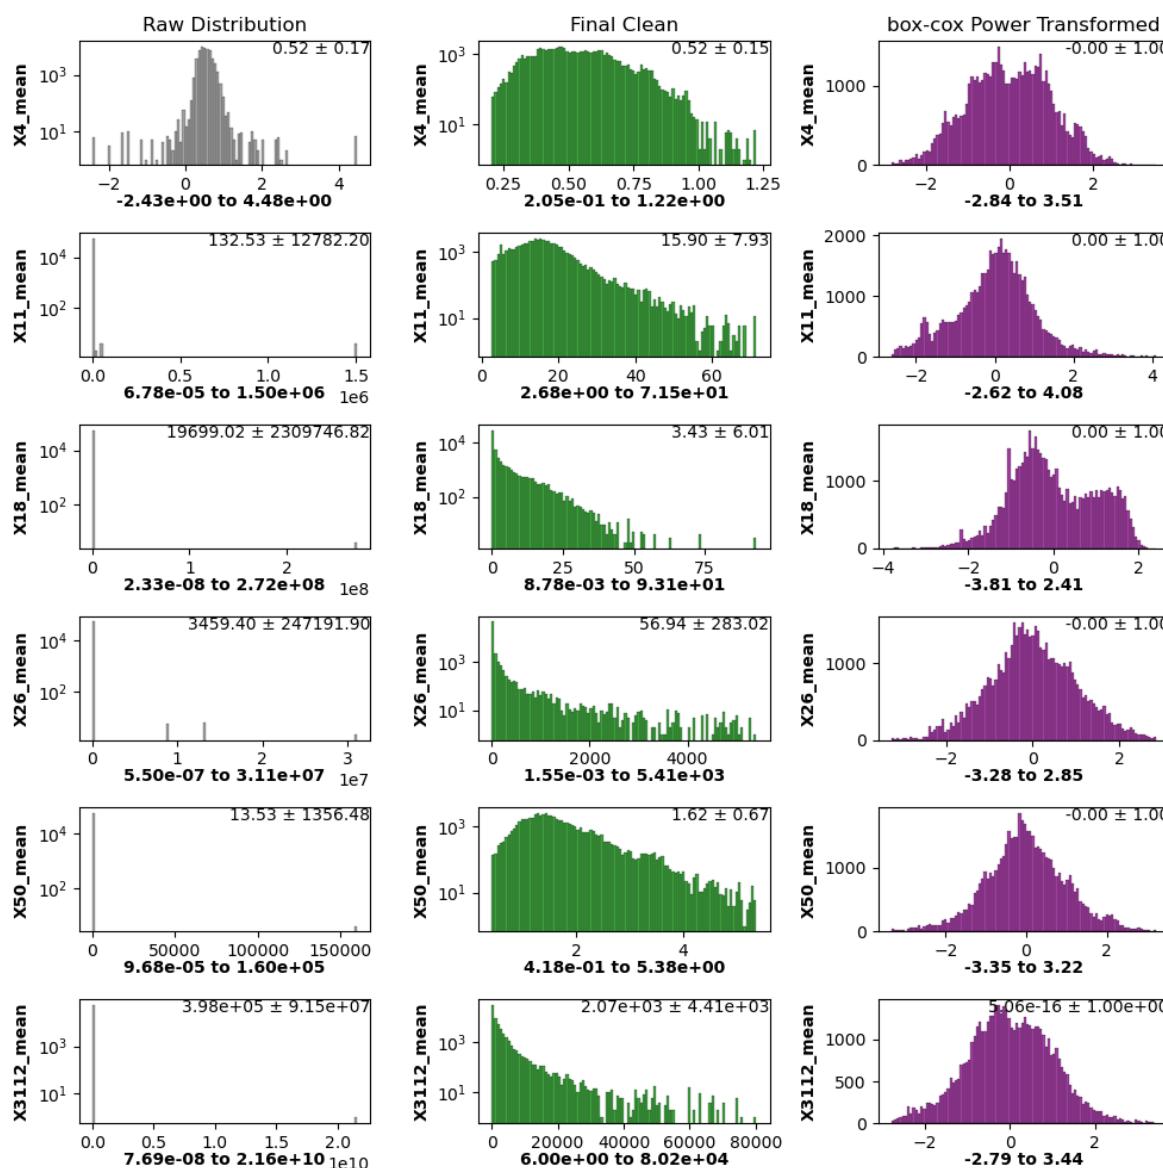

ID: 194951954 | 6.85e+05

Area = 6.9e5
Unlikely real value
Doesn't look leafy

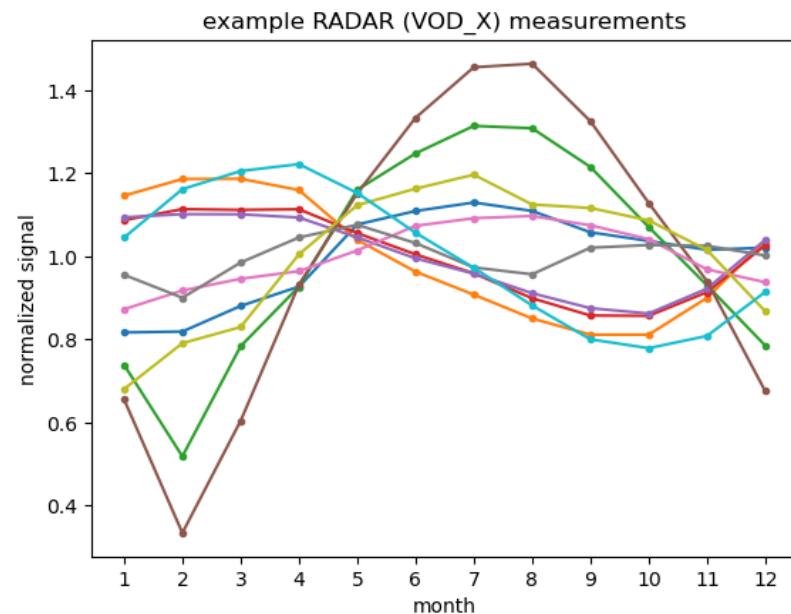

Plant Trait Target outlier removal

- As shown in previous slide, plant images investigated to establish reasonable cutoffs for each trait.
- Then, additional outliers were removed based on log transformed standard deviations away from mean (≥ 3 removed).
- Finally, a power transformation was applied to provide a more normal distribution for each trait.
 - Targets were inverse transformed prior to residuals analysis.

Seasonal Feature Engineering: RADAR + Satellite

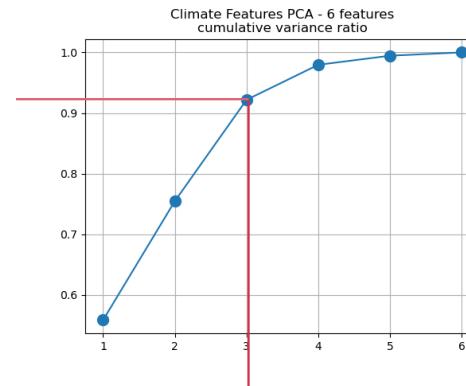

- Measurements are monthly means for various frequency bands
 - Satellite data provides sun reflectance information (5 bands, named by number)
 - Radar data provides water content, plant biomass information (3 bands: C, K_u, X)
- Inspired by provided climate data ([BIOCLIM](#)), engineered 3 features to replace each monthly measurement:
 - Max month – Min month (delta min,max)
 - Annual average
 - Seasonality (*standard deviation / mean*) [%]

Feature Decomposition – Principal Components Analysis

163 features → 21 PCA components

- PCA decomposition gave better model performance than other feature selection/elimination methods (tested with ElasticNet)
 - Sequential, Recursive, SelectFromModel
 - Makes sense as it should take more information into account
- Each feature group considered separately
 - Soil (10), Climate (3), Satellite (5), Radar (3)
- PCA components chosen to capture at least 90% of feature group variation. Components analyzed to ensure input features had appropriate representation.
- Engineered Satellite and Radar features used instead of monthly means.
- Correlations with target traits compared for raw features and for PCA features
 - Typically similar or higher for PCA

	PCA_1	PCA_2	PCA_3
BIO1	0.856	0.265	-0.609
BIO12	0.790	-0.476	0.856
BIO13.BIO14	0.846	0.166	1.000
BIO15	0.348	1.000	0.232
BIO4	-1.000	0.081	0.621
BIO7	-0.995	0.260	0.463

Climate Example
6 → 3

Total (R ²)
PCA_1 0.506617
PCA_3 0.088865
PCA_2 0.023678

Sum of each
target's R²

Model (CNN) Architecture

- Example shown for adapting [MobileNetV2](#)
 - Same idea for [InceptionResNetV2](#)
- Concatenated image branch and geodata branch after individual feature extraction / decomposition
- Fully connected dense layers for final prediction
- Combining two data streams for one final prediction was found to be more accurate than separate predictions, combined after the fact (ex: [VotingRegressor](#)).
 - Some tabular data (geodata) only models were more accurate when predicting traits sequentially

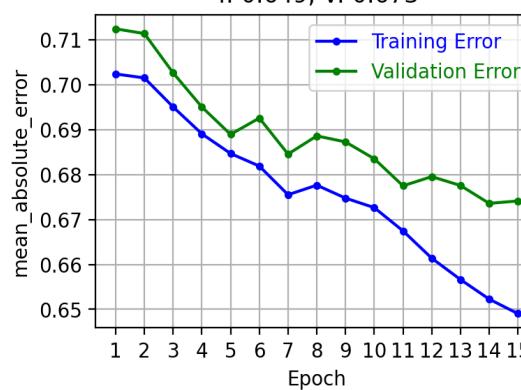

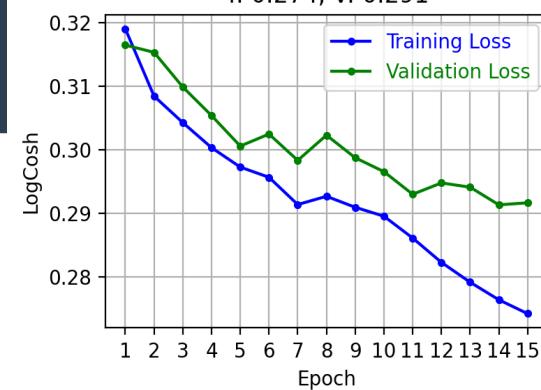

Modeling

Training Results

InceptionResNet | 299x299 | 124 min |
raw metrics T: 193, V: 192 | T: 193, V: 192

T: 0.274, V: 0.291

T: 0.649, V: 0.673

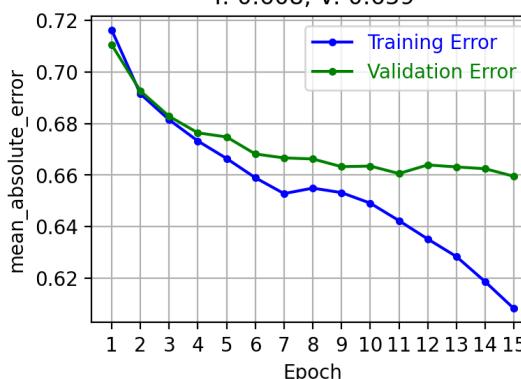

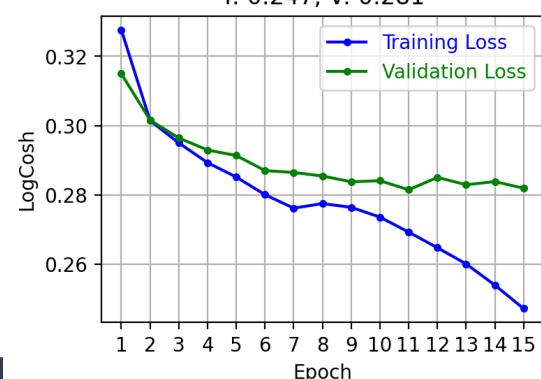

History plot metrics are for transformed targets

Title text provides 'raw metrics' (LogCosh | MAE) for the training and validation sets
Hold out test scores presented on next slide.

MobileNet15ep | 224x224 | 45 min |
raw metrics T: 216, V: 212 | T: 216, V: 213

T: 0.247, V: 0.281

T: 0.608, V: 0.659

Best two modeling attempts shown.
Conclusions from previous experiments:

- Existing architectures provide good baseline performance. (see: [Keras table](#))
 - ImageNet ranking does not correlate to this task. **MobileNetV2** outperformed all tested models except for **InceptionResNetV2**.
- Image augmentation and integrated **resize layer** help model performance.
- Fully retraining model weights boosts performance without taking more time.
- LogCosh good loss metric for raw target traits, limits influence of extreme values.
- Room for optimization and hyper-parameter tuning.

Final Model

justification for MobileNetV2

Metric	MobileNet	IncResNet	CatBoost
MAE	212	192	263
LogCosh	212	192	263
Time	45 mins	124 mins	40s

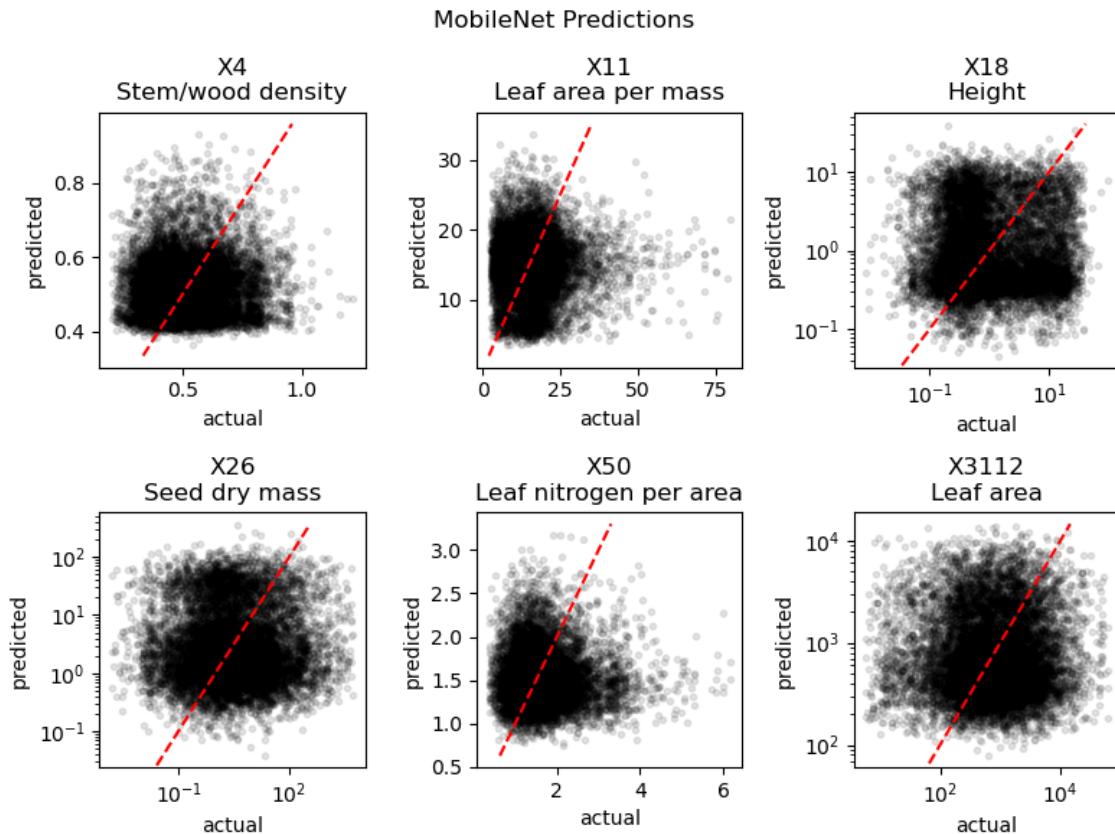

*Hold Out test results
(20% of data)*

- The paper this competition was inspired by ultimately choose InceptionResNetV2 for their CNN architecture. While this also gave me the best performance, I will select MobileNetV2 for my final model.
- Accuracy was not much worse, and training time was *much faster*. Additionally, the model itself is lighter (45 MB vs 840 MB).
- As my final work has not been fully optimized, the model using MobileNetV2's architecture will be more suitable for tuning, assuming development on a similar system.
 - More powerful systems could consider models I was not able to train.
- The following slides will present residual analysis from the MobileNet model.

Residual Analysis 1

errors (mostly) randomly distributed for the 6 plant traits

- Prediction range typically lower than actual range.
 - Does this indicate insufficient or poor outlier detection/cleaning?
- Plant Height seems to be more difficult to predict accurately, not quite random error.
 - L shape apparent. Accuracy worse for taller plants.
- Note log scale for Height, Seed dry mass and Leaf Area

Residual Analysis 2

image investigation – plant height ($X18_mean$) example | *worst predictions*

ID: 57277368 | error: -38.43
actual 0.21 | pred 38.64

ID: 195183053 | error: -22.57
actual 0.16 | pred 22.73

ID: 187984198 | error: -22.21
actual 0.50 | pred 22.71

ID: 193095817 | error: -20.77
actual 0.16 | pred 20.93

ID: 168686898 | error: 49.17
actual 52.73 | pred 3.55

ID: 195410258 | error: 62.13
actual 62.77 | pred 0.65

ID: 195584787 | error: 67.21
actual 72.78 | pred 5.56

ID: 191433347 | error: 85.38
actual 93.10 | pred 7.71

- Largest (4) over-predictions on top row, largest (4) under-predictions on bottom row.
- Makes sense for model to struggle with images showing only subset of plant.
- Should future preprocessing / cleaning consider image quality?
 - Ex: if ImageNet identifies an image as a “hand”, don’t use.

Residual Analysis 3

image investigation – leaf area (*X3112_mean*) example | *best predictions*

Leaf area lowest residuals

ID: 193399574 | error: 0.10
actual 310.31 | pred 310.41

ID: 193120422 | error: 0.10
actual 1061.39 | pred 1061.49

ID: 180135885 | error: 0.12
actual 289.84 | pred 289.72

ID: 194861938 | error: 0.18
actual 1320.06 | pred 1319.89

ID: 180522441 | error: 0.18
actual 270.54 | pred 270.36

ID: 168856208 | error: 0.29
actual 1398.29 | pred 1398.01

ID: 194006317 | error: 0.32
actual 1084.71 | pred 1084.39

ID: 176161952 | error: 0.41
actual 656.99 | pred 656.58

- Best (8) predictions based on absolute error.
- Encouraging to see accuracy at different magnitudes of leaf area (*trait range ~ 10⁴*).
- Two of best predictions are from image containing a hand.
 - Maybe cleaning should not be as simple as suggested on the last slide.
 - Do hands affect some traits more than others?

Model Refinement

model and data cleaning still have room for improvement

- Continue developing cleaning methods for training data. Focus on images. More specific target outlier assessment.
 - Wide variety of images should be part of a training set, given “citizen-science” problem statement. But not all the images need be used for model training.
 - Given my lack of domain knowledge, identifying plant trait outliers or faulty data was “handwavy”. Subject matter expertise should improve this process.
- Target Trait plasticity
 - Plant traits are provided as a mean measurement. Previous work found benefit to “plasticizing” these values with the traits’ standard deviations, something which I did not try for this project.
- CNN model hyperparameter tuning. More training epochs.
 - Given long training time, I focused on “big” pieces for experimentation, like the choice of transferred CNN architecture.
 - More handles can be turned to tune model performance, like choice of optimizer, loss and metric functions, learning rate schedules, feature averaging techniques, dropout layers, activation functions, etc. . .
- Species identification: Should help model performance, as species and close relations will have similar traits.
- Transformer Models: I focused on CNN architectures for this project.

Project Implications

- My work, in addition to that of **all the Kaggle competitors**, provides an important start to utilizing citizen sourced data for measuring the health of Earth's ecosystems.
- High accuracy was not expected as part of the project design, but analysis of the images with the highest residuals could improve future data cleaning efforts.
- The data cleaning, feature engineering, feature decomposition, and feature combination streams employed prior to model training will benefit future, similar projects.

Acknowledgments

- **Aditya Bhattacharya**

Thank you for your mentorship and guidance throughout the project!

- **Kaggle Competition, Paper Authors**

The competition and paper provided a great template for this work, and the competitors helped me get started with the data and modeling. Thank you [Rich Olson](#) for your helpful discussions and shared work.

- **Springboard Curriculum**

The [guided capstone project](#) served as a useful guide for this project.
